ABSTRACT

I summarize some recent results obtained in collaboration with P. Bouwknegt and K. Pilch on the spectrum of physical states in $\mathcal{W}_3$ gravity coupled to $c = 2$ matter. In particular, it is shown that the algebra of operators corresponding to physical states – defined as a semi-infinite (or BRST) cohomology of the $\mathcal{W}_3$ algebra – carries the structure of a G-algebra. This G-algebra has a quotient which is isomorphic to the G-algebra of polyvector fields on the base affine space of $SL(3, \mathcal{C})$. Details will appear elsewhere.

1. Introduction and preliminaries

W-gravity models are reparametrization-invariant field theories in which the vector-generated diffeomorphism symmetry is extended by higher tensor structures. For example, while a scalar field transforms under an infinitesimal diffeomorphism by the vector $\xi^\mu(x)$, $x'^\mu = x^\mu + \xi^\mu(x)$, as $\delta\phi(x) = \xi^\mu(x)\partial_\mu\phi(x)$, in a W-gravity there would be additional invariances which at the linearized level act as

$$\delta\phi(x) = \xi^{\mu_1\cdots\mu_n}(x)\partial_{\mu_1}\cdots\partial_{\mu_n}\cdots\phi(x)$$

for some integer $n > 1$. Just as diffeomorphisms are associated with massless particles of spin two, *i.e.* metric fluctuations, so also W-gravities lead to theories of massless higher-spin fields. The goal of constructing a non-trivial interacting QFT with massless higher-spin fields in four dimensional spacetime has proved to be rather elusive, so it is not surprising that very little is known about W-gravities there.

Quite recently, progress has been made on the problem of constructing $\mathcal{W}$ -gravities in two dimensions. Classically such models are somewhat trivial, since – as for ordinary 2-d gravity – a simple counting shows that there are no propagating gravitational degrees of freedom after accounting for gauge invariances (see ¹ and references therein). However, upon quantization there are two possibilities which are both of interest: either the decoupling of the $\mathcal{W}$ -gravitational degrees of freedom is maintained, providing a generalization of the world-sheet reparametrization invariance in the first-quantized description of string theory and thus possibly new critical

string theories; or the decoupling is not maintained, and some $\mathcal{W}$ -gravitational fields become propagating due to quantum corrections as in the so-called off-critical theories. In either case, these models provide a mathematical physics laboratory to study the fascinating problem of quantizing a gauge theory based on a non-linear algebra of constraints – a $\mathcal{W}$ -algebra extension of the Virasoro algebra.

It is this algebraic structure which provides a definition of $\mathcal{W}$ -gravity models even though the associated $\mathcal{W}$ -geometry is not yet well understood. In particular, by analogy with the standard DDK ansatz for 2-d gravity^{2 3}, there exists a well-motivated BRST-quantization of $\mathcal{W}_3$ -gravity coupled to conformal matter with central charge less than or equal to two^{4,5,6}. So, there is a nilpotent BRST charge d , $d^2 = 0$, and the physical state subspace is defined by the condition $d|phys\rangle = 0$, modulo the equivalence relation $|phys\rangle \sim |phys\rangle + d|\chi\rangle$. In other words, a physical state is a representative of a BRST cohomology class. Although (unlike the DDK case) calculating the physical spectrum of these $\mathcal{W}$ -gravity models seems extremely difficult, it is reasonable to expect that the study of this cohomology space will lead to a better understanding of (quantum) $\mathcal{W}$ -geometry.

In this paper I partially summarize work on this problem done in collaboration with Peter Bouwknegt and Krzysztof Pilch. I restrict the discussion to one model: $\mathcal{W}_3$ -gravity coupled to a matter sector consisting of two scalar fields ($c^M = 2$). In the corresponding string theory these scalar fields would embed the world sheet of the string into a two dimensional space-time. But, moreover, since this is a non-critical theory there are dynamical gravitational degrees of freedom which under the DDK-type ansatz are described by a pair of scalar fields of “wrong sign” with a background charge source, the so-called Liouville sector. Thus, in this string language, the model describes a $2+2$ dimensional string in non-trivial background fields. In a conformal gauge quantization of this string the calculation splits into almost decoupled left- and right-moving sectors, the physical states are then computed from the BRST cohomology of a tensor product of two scalar field Fock space modules of the $\mathcal{W}_3$ algebra.

In Section 2 I present more clearly the cohomology problem which is required to compute the physical spectrum of the $D = 2+2$ $\mathcal{W}_3$ string. The complete result for this cohomology is given at the start of Section 3, followed by some justification for a special set which is picked out in analogy with the “Seiberg bound” of the DDK case⁷. I then discuss in Section 4 the structure of the corresponding operator cohomology as a Gerstenhaber (G-) algebra. In particular, the special case selected above is shown to be geometrically modeled by the G-algebra of regular polyvector fields on the base affine space of $SL(3, \mathcal{C})$. For more details the reader is referred to the literature^{6 8 9} and the forthcoming paper¹⁰.

Throughout this paper I will use the notation $\mathbf{h}$ for the Cartan subalgebra, $\mathbf{h}_{\mathbb{Z}}^*$ for the set of integral weights, P_+ for the set of dominant integral weights, P_{++} for the set of strictly dominant integral weights.

2. Fock space BRST complex for the $\mathcal{W}_3$ algebra

The $\mathcal{W}_3$ algebra with central charge $c \in \mathcal{C}$ (see *e.g.* the review on $\mathcal{W}$ -algebras¹¹, and references therein) is generated by the operators L_n and W_n , $n \in \mathbb{Z}$,

$$\begin{aligned} [L_m, L_n] &= (m-n)L_{m+n} + \frac{c}{12}m(m^2-1)\delta_{m+n,0} \\ [L_m, W_n] &= (2m-n)W_{m+n} \\ [W_m, W_n] &= (m-n)\left(\frac{1}{15}(m+n+3)(m+n+2) - \frac{1}{6}(m+2)(n+2)\right)L_{m+n} \\ &\quad + \beta(m-n)\Lambda_{m+n} + \frac{c}{360}m(m^2-1)(m^2-4)\delta_{m+n,0}, \end{aligned} \quad (1)$$

where $\beta = 16/(22+5c)$ and

$$\Lambda_m = \sum_{n \leq -2} L_n L_{m-n} + \sum_{n > -2} L_n L_{m-n} - \frac{3}{10}(m+3)(m+2)L_m.$$

As for Lie algebras the commutators of generators satisfy the Jacobi identities, but the $\mathcal{W}$ -algebras are clearly distinguished from Lie algebras by their nonlinear structure. The generators of the algebra $\mathcal{W}_3$ may be decomposed according to the $(-\text{ad } L_0)$ eigenvalue, $\mathcal{W}_+ \oplus \mathcal{W}_0 \oplus \mathcal{W}_-$, where $\mathcal{W}_\pm = \{L_n, W_n \mid \pm n > 0\}$ and the Cartan subalgebra $\mathcal{W}_0$ is spanned by L_0 and W_0 . This is not a usual triangular decomposition with respect to $\mathcal{W}_0$ – in particular, $(\text{ad } W_0)$ is not diagonalizable.

Despite these differences, a non-trivial BRST cohomology may be defined for $\mathcal{W}_3$ by analogy with that for the Virasoro algebra. Corresponding to the two sets of generators L_m and W_m , $m \in \mathbb{Z}$, introduce two sets of ghost oscillators $(b_m^{[i]}, c_m^{[i]})$, $i = 2, 3$ with anticommutation relations $\{c_m^{[i]}, b_n^{[i']}\} = \delta^{ii'} \delta_{m+n,0}$. The ghost Fock space F^{gh} is graded by the ghost number $\text{gh}(\cdot)$, where $\text{gh}(c_n^{[i]}) = -\text{gh}(b_n^{[i]}) = 1$, while the ghost number of the $(sl(2, \mathcal{C})$ -invariant) vacuum state is zero. For any two positive energy^a $\mathcal{W}$ -modules V^M and V^L , such that $c^M + c^L = 100$, there exists a complex $(V^M \otimes V^L \otimes F^{\text{gh},n}, d)$, graded by ghost number, and with a differential (BRST operator) d of degree 1,

$$\begin{aligned} d &= \sum_m (c_{-m}^{[3]}(\widetilde{W}_m^M - i\widetilde{W}_m^L) + c_{-m}^{[2]}(L_m^M + L_m^L)) \\ &\quad + \sum_{m,n} \left(-\frac{1}{2}(m-n)c_{-m}^{[2]}c_{-n}^{[2]}b_{m+n}^{[2]} - (2m-n)c_{-m}^{[2]}c_{-n}^{[3]}b_{m+n}^{[3]} \right. \\ &\quad \left. - \frac{1}{6}\mu(m-n)(2m^2 - mn + 2n^2 - 8)c_{-m}^{[3]}c_{-n}^{[3]}b_{m+n}^{[2]} \right) \\ &\quad + \sum_{m,n,p} \left(-\frac{1}{2}(m-n)c_{-m}^{[3]}c_{-n}^{[3]}b_{-p}^{[2]}(L_{m+n+p}^M - L_{m+n+p}^L) \right), \end{aligned} \quad (2)$$

where $\widetilde{W}^{M,L} = W^{M,L}/\sqrt{\beta^{M,L}}$ and $\mu = (1 - 17\beta^M)/(10\beta^M)$. The cohomology of d at degree n will be denoted by $H^n(\mathcal{W}, V^M \otimes V^L)$, and called the BRST cohomology of the $\mathcal{W}_3$ algebra on $V^M \otimes V^L$.

^aA positive energy module has L_0 diagonalizable with finite dimensional eigenspaces, and with the spectrum bounded from below.

In this paper I will discuss the case in which both V^M and V^L are free scalar field Fock space modules of the $\mathcal{W}$ -algebras. Let $\phi^i(z)$, $i = 1, 2$ be two free scalar fields normalized such that $\phi^i(z)\phi^j(w) = -\delta^{ij} \ln(z-w) + \text{regular}$, and coupled to a background charge $\alpha_0\rho$, where $\rho = \alpha_1 + \alpha_2$ is the principal vector of the Lie algebra sl_3 . In other words, the stress-energy tensor, $T(z)$, has the “improved” form

$$T(z) = -\frac{1}{2}(\partial\phi(z), \partial\phi(z)) - i\alpha_0(\rho, \partial^2\phi(z)).$$

One easily checks from Wick’s theorem that $T(z)T(w) = \frac{c(\alpha_0)/2}{(z-w)^4} + \frac{2}{(z-w)^2}T(w) + \frac{1}{z-w}\partial T(w) + \text{regular}$, where $c(\alpha_0) = 2 - 24\alpha_0^2$. Decomposing in modes, $T(z) = \sum L_n z^{-n-2}$, this is equivalent to the statement that the L_n generate a Virasoro algebra of central charge $c(\alpha_0)$. The extension to a realization of the full $\mathcal{W}_3$ algebra is similarly encoded in the spin-3 chiral current (after a choice of orthonormal basis with respect to which the simple roots of sl_3 are $\alpha_1 = (\sqrt{2}, 0)$, $\alpha_2 = (-\frac{1}{\sqrt{2}}, \frac{\sqrt{3}}{\sqrt{2}})$)

$$\begin{aligned} \frac{1}{\sqrt{3\beta}}W(z) &= \frac{-i}{3\sqrt{6}}(\partial\phi^1\partial\phi^1\partial\phi^2 - \partial\phi^2\partial\phi^2\partial\phi^2) + \\ &\alpha_0\left(\frac{1}{2}\partial\phi^1\partial^2\phi^1 + \frac{1}{\sqrt{3}}\partial\phi^2\partial^2\phi^1 - \frac{1}{2}\partial\phi^2\partial^2\phi^2\right) + \frac{i}{2\sqrt{2}}\alpha_0^2(\partial^3\phi^1 - \frac{1}{\sqrt{3}}\partial^3\phi^2). \end{aligned}$$

The expansion of ϕ^j into modes is given by

$$\phi^j(z) = \phi_0^j - i p^j \log z + i \sum_{n \neq 0} \alpha_n^j z^{-n}.$$

Let $\mathcal{F}(\Lambda, \alpha_0)$ denote the Fock space of these 2 scalar fields, where Λ – the “momentum” vector – labels the Fock space vacuum $|\Lambda\rangle$ defined by $p^i|\Lambda\rangle = \Lambda^i|\Lambda\rangle$ and $\alpha_n|\Lambda\rangle = 0$, $n > 0$. As a $\mathcal{W}_3$ module the Fock space is highest-weight, with

$$\begin{aligned} L_0|\Lambda\rangle &= h(\Lambda)|\Lambda\rangle = \frac{1}{2}(\Lambda, \Lambda + 2\alpha_0\rho)|\Lambda\rangle \\ W_0|\Lambda\rangle &= w(\Lambda)|\Lambda\rangle = \sqrt{3\beta}\theta_1\theta_2\theta_3|\Lambda\rangle, \end{aligned} \quad (3)$$

where (the weights Λ_1 and Λ_2 are the fundamental weights of sl_3)

$$\theta_1 = (\Lambda + \alpha_0\rho, \Lambda_1), \quad \theta_2 = (\Lambda + \alpha_0\rho, \Lambda_2 - \Lambda_1), \quad \theta_3 = (\Lambda + \alpha_0\rho, -\Lambda_2).$$

It is important to note that both $h(\Lambda)$ and $w(\Lambda)$ in (3) determine Λ only up to a Weyl rotation $\Lambda \rightarrow w(\Lambda + \alpha_0\rho) - \alpha_0\rho$, $w \in W$.

Finally, then, the case of interest here is $\alpha_0^M = 0$ and $-i\alpha_0^L = 2$, *i.e.* $c^M = 2$, $c^L = 98$. The Fock space momenta are *a priori* free, however it turns out that without loss of generality the momenta may be restricted to the sl_3 weight lattice. Thus the cohomology to be discussed is

$$\mathcal{H} \equiv \bigoplus_{(\Lambda^M, -i\Lambda^L) \in \mathbf{h}_{\mathbb{Z}}^* \otimes \mathbf{h}_{\mathbb{Z}}^*} H(\mathcal{W}, F(\Lambda^M, 0) \otimes F(\Lambda^L, 2i)). \quad (4)$$

3. Physical states of the $D = 2 + 2 \mathcal{W}_3$ string

The following result summarizes the solution^{6 8} to the cohomology problem (4) posed in the previous section.

Theorem 1 For the cohomology (4) with differential (2),

(i) $\mathcal{H}$ carries the structure of a $\mathfrak{g} \oplus \mathfrak{h}$ module ($\mathfrak{g} \cong \mathfrak{sl}_3$, $\mathfrak{h} \cong u_1 \oplus u_1$). This module is completely reducible under $\mathfrak{g} \oplus \mathfrak{h}$.

(ii) There exists a (non-canonical) isomorphism (as $\mathfrak{g} \oplus \mathfrak{h}$ modules)

$$\mathcal{H}^i \cong \mathcal{H}_{\text{pr}}^i \oplus \mathcal{H}_{\text{pr}}^{i-1} \oplus \mathcal{H}_{\text{pr}}^{i-1} \oplus \mathcal{H}_{\text{pr}}^{i-2}.$$

The cohomology $\mathcal{H}_{\text{pr}}$ is isomorphic (as a $\mathfrak{g} \oplus \mathfrak{h}$ module) to the direct sum of irreducible modules $\mathcal{L}(\Lambda) \otimes \mathcal{C}_{\Lambda'}$ with momenta $(\Lambda, \Lambda') \in \mathfrak{h}_{\mathbb{Z}}^* \otimes \mathfrak{h}_{\mathbb{Z}}^*$ lying in a set of disjoint cones $\{\mathcal{S}_w^n + (\lambda, w^{-1}\lambda) \mid \lambda \in P_+\}$, i.e.

$$\mathcal{H}_{\text{pr}}^n \cong \bigoplus_{w \in W} \bigoplus_{(\Lambda, \Lambda') \in \mathcal{S}_w^n} \bigoplus_{\lambda \in P_+} (\mathcal{L}(\Lambda + \lambda) \otimes \mathcal{C}_{\Lambda' + w^{-1}\lambda}),$$

where the sets $\mathcal{S}_w^n$ (tips of the cones) are given in Table 1.

n	w	$\mathcal{S}_w^n$
0	1	(0, 0)
1	1 r_1 r_2	$(\Lambda_1, -\Lambda_1 + \Lambda_2), (\Lambda_1 + \Lambda_2, 0), (\Lambda_2, \Lambda_1 - \Lambda_2)$ $(0, -2\Lambda_1 + \Lambda_2)$ $(0, \Lambda_1 - 2\Lambda_2)$
2	1 r_1 r_2 $r_1 r_2$ $r_2 r_1$	$(2\Lambda_1, -\Lambda_1), (0, -\Lambda_1 - \Lambda_2), (2\Lambda_2, -\Lambda_2)$ $(\Lambda_1, -2\Lambda_1), (\Lambda_2, -3\Lambda_1 + \Lambda_2), (0, -4\Lambda_1 + 2\Lambda_2)$ $(\Lambda_2, -2\Lambda_2), (\Lambda_1, \Lambda_1 - 3\Lambda_2), (0, 2\Lambda_1 - 4\Lambda_2)$ $(0, -3\Lambda_2)$ $(0, -3\Lambda_1)$
3	1 r_1 r_2 $r_1 r_2$ $r_2 r_1$ $r_1 r_2 r_1$	$(\Lambda_1 + \Lambda_2, -\Lambda_1 - \Lambda_2)$ $(\Lambda_2, -2\Lambda_1 - \Lambda_2), (\Lambda_1, -4\Lambda_1 + \Lambda_2), (\Lambda_2, -5\Lambda_1 + 2\Lambda_2)$ $(\Lambda_1, -\Lambda_1 - 2\Lambda_2), (\Lambda_2, \Lambda_1 - 4\Lambda_2), (\Lambda_1, 2\Lambda_1 - 5\Lambda_2)$ $(\Lambda_2, -\Lambda_1 - 3\Lambda_2), (0, \Lambda_1 - 5\Lambda_2), (\Lambda_2, -5\Lambda_2)$ $(\Lambda_1, -3\Lambda_1 - \Lambda_2), (0, -5\Lambda_1 + \Lambda_2), (\Lambda_1, -5\Lambda_1)$ $(0, -2\Lambda_1 - 2\Lambda_2)$
4	r_1 r_2 $r_1 r_2$ $r_2 r_1$ $r_1 r_2 r_1$	$(0, -4\Lambda_1 - \Lambda_2)$ $(0, -\Lambda_1 - 4\Lambda_2)$ $(\Lambda_2, -2\Lambda_1 - 4\Lambda_2), (\Lambda_1, -\Lambda_1 - 5\Lambda_2), (0, -6\Lambda_2)$ $(\Lambda_1, -4\Lambda_1 - 2\Lambda_2), (\Lambda_2, -5\Lambda_1 - \Lambda_2), (0, -6\Lambda_1)$ $(0, -3\Lambda_1 - 3\Lambda_2), (2\Lambda_1, -4\Lambda_1 - 3\Lambda_2), (2\Lambda_2, -3\Lambda_1 - 4\Lambda_2)$
5	$r_1 r_2$ $r_2 r_1$ $r_1 r_2 r_1$	$(0, -2\Lambda_1 - 5\Lambda_2)$ $(0, -5\Lambda_1 - 2\Lambda_2)$ $(\Lambda_1, -5\Lambda_1 - 3\Lambda_2), (\Lambda_1 + \Lambda_2, -4\Lambda_1 - 4\Lambda_2), (\Lambda_2, -3\Lambda_1 - 5\Lambda_2)$
6	$r_1 r_2 r_1$	$(0, -4\Lambda_1 - 4\Lambda_2)$

Table 1. The sets $\mathcal{S}_w^n$

The action of $\mathfrak{g}$ is via the zero modes of the Frenkel-Kac-Segal vertex operator construction of level 1 affine $su(3)$ (using only the $\alpha_0^M = 0$ matter fields of course), while $\mathfrak{h}$ acts as $-ip^L$ (with eigenvalues $-i\Lambda^L$). One easily checks directly that these are non-trivial operators which commute with d . That leaves the computation in

(ii). [Note that the quartet structure in terms of so-called “prime” states is a nontrivial result, and not an immediate consequence of a relation between the full cohomology and some relative subcomplex.]

For the Virasoro case¹² it was straightforward to work with the Fock space oscillators. The basic observation is well illustrated in calculating the cohomology of $d_0 = ca^\dagger$ on the Fock space of a single oscillator, $[a, a^\dagger] = 1$, $\{b, c\} = 1$. The only non-trivial cohomology state is clearly the state $c|0\rangle$ where $a|0\rangle = b|0\rangle = 0$ (any Fock space state of the form $c\psi\rangle$ is annihilated by d , but on modding out the d -exact states only $c|0\rangle$ is non-trivial). Thus one simply has to introduce a degree on the space of oscillators for which the lowest degree term in d has the form of d_0 for each oscillator. The higher degree terms then act trivially and the full cohomology is again just one dimensional. A modification of this idea completely solves the Virasoro case. Unfortunately, for the $\mathcal{W}$ case it does not seem possible to assign a degree which is even close to working in the same way, and one must find other techniques (there are alternative discussions for the Virasoro case¹³, see also¹⁴).

As mentioned in the introduction, for this paper I will only discuss the justification of (ii) in the case that $-i\Lambda^L + 2\rho \in P_+$, which is essentially $w = 1$ in the above. The other sectors are deduced from a conjecture based on generic results for $c^M < 2$, together with the $w = 1$ sector result, and there is not enough space here to motivate this conjecture properly.

3.1. The case $-i\Lambda^L + 2\rho \in P_+$

The $d_0 = ca^\dagger$ cohomology for a single oscillator, as discussed above, was simple to calculate because the Fock module has a particularly simple structure – it is free over $a^\dagger$ – which “fits” the form of d_0 . For the $\mathcal{W}$ -algebra computation d has the form “ $d \sim c_{-n}^{[2]}L_n + c_{-n}^{[3]}W_n + \dots$ ”, so it is natural to calculate the cohomology where V^M and V^L are modules free over part of the $\mathcal{W}_3$ -algebra. A Verma module $M(h, w, c)$ is defined as the module induced by $\mathcal{W}_-$ from an eigenstate of $\mathcal{W}_0$, $|h, w\rangle$, (i.e. free over $\mathcal{W}_-$ with a single generator). The contragradient Verma module is denoted by $\overline{M}(h, w, c)$. A slight generalization arises naturally in considering the submodule structure of a Verma module: Due to the non-diagonalizability of W_0 it is useful to define the *generalized Verma module*, $M(h, w, c)_N$, as the positive energy module induced from an N -dimensional indecomposable representation of $\mathcal{W}_0$. Let $v_0, \dots, v_{N-1}$ be a canonical basis such that

$$\begin{aligned} L_0 v_i &= h v_i, \quad i = 0, \dots, N-1, \\ W_0 v_0 &= w v_0, \quad W_0 v_i = w v_i + v_{i-1}, \quad i = 1, \dots, N-1. \end{aligned} \quad (5)$$

Then $M(h, w, c)_N$ is spanned by the monomials of the form

$$L_{-n_1} \dots L_{-n_i} W_{-m_1} \dots W_{-m_j} v_k, \quad i, j \geq 0, \quad k = 0, \dots, N-1,$$

on which the generators in $\mathcal{W}_-$ act freely, while the action of those in $\mathcal{W}_+$ and $\mathcal{W}_0$ is determined using (1), (5), and

$$L_n v_i = W_n v_i = 0, \quad n > 0, \quad i = 0, \dots, N-1.$$

For $N = 1$ the usual definition of the Verma module $M(h, w, c)$ is clearly recovered.

Taking V^M and V^L as contragrediently-related (generalized) Verma modules, the cohomology of d is quite easily calculated via the introduction of an appropriate degree.

Lemma 1

The cohomology $H(\mathcal{W}, M(h(\Lambda^M), w(\Lambda^M), c(\alpha_0^M)))_N \otimes \overline{M}(h(\Lambda^L), w(\Lambda^L), c(\alpha_0^L))$ is non-vanishing if and only if $-i(\Lambda^L + \alpha_0^L \rho) = w(\Lambda^M + \alpha_0^M \rho)$ for some $w \in W$, in which case it is spanned by the states v_0 , $c_0^{[2]}v_0$, $c_0^{[3]}v_{N-1}$ and $c_0^{[2]}c_0^{[3]}v_{N-1}$, where $v_i = v_i^M \otimes \bar{v}^L \otimes |0\rangle_{gh}$.

This result still seems quite far from the Fock space calculation required, however there are three observations on Fock space modules $F(\Lambda, \alpha_0)$ which make it immediately applicable. The first two are reasonably standard to prove using the free field realization and the existence of a Hermitian inner product for $c = 2$.

Lemma 2

- (i) For $-i\Lambda^L + 2\rho \in P_+$ there is an isomorphism $F(\Lambda^L, 2i) \cong \overline{M}(h(\Lambda^L), w(\Lambda^L), 98)$.
- (ii) For $c = 2$, the Fock space $F(\lambda, 0)$ is completely reducible. Explicitly, for all $\lambda \in \mathbf{h}_{\mathbb{Z}}^*$, the Fock spaces decomposes as

$$F(\lambda, 0) \cong \bigoplus_{\Lambda \in P_+} m_{\lambda}^{\Lambda} L(h(\Lambda), w(\Lambda), 2),$$

where m_{λ}^{Λ} is equal to the multiplicity of the weight λ in the irreducible finite dimensional representation $\mathcal{L}(\Lambda)$ of $\mathfrak{sl}_3$ with highest weight Λ .

The last observation⁸ is that for $c = 2$ one may find resolutions of $L(\Lambda)$ in terms of (generalized) Verma modules $M(h, w, c = 2)_N$, i.e. there is a complex (of finite length),

$$0 \rightarrow \mathcal{C}^0 \rightarrow \mathcal{C}^1 \rightarrow \dots,$$

where the $\mathcal{C}^i$ are a finite direct sum of generalized Verma modules, the maps are embeddings, and where the non-trivial cohomology is at $\mathcal{C}^0 = M(h, w, c = 2)$ and is given by the irreducible representation $L(h, w, c = 2)$ (a slight misprint⁸ in the resolution of $L(\Lambda)$ for $\Lambda \in P_{++}$ has been corrected¹⁰). This result is, strictly speaking, conjectural, but has been tested by quite exhaustive MathematicaTM calculation.

Figuratively speaking, the following steps have been applied to this stage (using $H_d(\cdot)$ to denote $H(\mathcal{W}, \cdot)$, and H_{δ} to denote the cohomology in the resolution of the irreducible representation as discussed above):

$$H_d(F \otimes F) = \oplus H_d(L \otimes \overline{M}) = \oplus H_d H_{\delta}(M_N \otimes \overline{M}) = \oplus H_{\delta} H_d(M_N \otimes \overline{M}).$$

The cohomology on the left is the required Fock space cohomology, while that on the right is known from Lemma 1. The exchange of orders in calculating the cohomology is allowed, basically because after grading by L_0 every computation can be reduced to one on finite dimensional vector spaces. Thus, the Fock space cohomology for

$-i\Lambda^L + 2\rho \in P_+$ may now be rather simply re-assembled by simply going backwards in these steps.

4. The operator algebra

In this final section I will try to give the flavour of the type of result which can be obtained on the operator algebra. Analogous results for the Virasoro case may be found in ^{15 16 17}. I will not attempt to give a complete result since that requires quite a deal of mathematical preliminaries.

Given a state $|\mathcal{O}\rangle$ in the BRST complex, one may assign an operator $\mathcal{O}(z)$ such that

$$|\mathcal{O}\rangle = \lim_{z \rightarrow 0} \mathcal{O}(z)|0\rangle.$$

The operator product expansions of these operators are graded commutative (graded by ghost number) and associative – these are just statements about free fields. Perhaps the only subtlety is the existence of “phase-cocycles”, which are required to ensure mutual locality.

To explain this, let me consider as an example the operator corresponding to the Fock space state $|\Lambda^M, \Lambda^L\rangle$, which is naively the normal-ordered exponential

$$V_A(z) =: e^{i(\Lambda_A^M, \phi^M(z)) + i(\Lambda_A^L, \phi^L(z))} :.$$

It is easily verified that

$$V_A(z)V_B(w) = (z-w)^{h_{AB}} : e^{i(\Lambda_A^M, \phi^M(z)) + i(\Lambda_A^L, \phi^L(z)) + i(\Lambda_B^M, \phi^M(w)) + i(\Lambda_B^L, \phi^L(w))} :, \quad (6)$$

where $h_{AB} = (\Lambda_A^M, \Lambda_B^M) + (\Lambda_A^L, \Lambda_B^L)$, as an operator product expansion – *i.e.* for $|z| > |w|$ the product is just composition of operators, but for the remainder it is defined by analytic continuation. However, the phase introduced by the $(z-w)$ factor will not in general be consistent with (6), analytic continuation, and $V_A(z)V_B(w) = V_B(w)V_A(z)$. To account for the phase, one replaces the exponential by

$$\mathcal{V}_A(z) = V_A(z) e^{i\pi \xi_A^M \cdot p^M + i\pi \xi_A^L \cdot p^L},$$

where the phase-cocycles are chosen so that

$$\xi_A^M \cdot \Lambda_B^M + \xi_A^L \cdot \Lambda_B^L - \xi_B^M \cdot \Lambda_A^M - \xi_B^L \cdot \Lambda_A^L = \Lambda_A^M \cdot \Lambda_B^M + \Lambda_A^L \cdot \Lambda_B^L \pmod{2}.$$

Thus, the problem of constructing an operator product algebra basically reduces to finding such phase-cocycles – which is relatively straightforward. In the present case, this requires restriction of the momenta $(\Lambda^M, -i\Lambda^L)$ to the lattice L , where

$$L \equiv \{(\lambda, \mu) \in \mathbf{h}_{\mathbb{Z}}^* \otimes \mathbf{h}_{\mathbb{Z}}^* \mid \lambda - \mu \in \mathbb{Z} \cdot \Delta_+\}.$$

This restriction is already required to produce a vertex operator algebra whose operator product expansion with the cohomology is meromorphic. I will denote the operator product algebra corresponding to the BRST complexes based on Fock

spaces with weights in the lattice L by $\mathcal{A}_L$. Indeed to construct the analogue of the cohomology problem (4) the direct sum should, strictly speaking, be restricted to weights in the lattice L . As is clear from the results in Section 3 this does not involve any loss of generality.

The BRST operator d acts on $\mathcal{A}_L$ by commutator – equivalently, let $J(z)$ be the BRST current, then the action of d is given by

$$\oint_{C_z} \frac{dx}{2\pi i} J(x) \mathcal{O}(z),$$

where the contour C_z surrounds the point $x = z$ counterclockwise. The operator cohomology, $\mathcal{H}_{op}$, is isomorphic to the physical states of Section 2. When I talk about an operator in $\mathcal{H}_{op}$ I will mean an element of $\mathcal{A}_L$ which is a representative of operator cohomology in the same sense that a physical state is a representative of $H(\mathcal{W}, F^M \otimes F^L)$. There is a Virasoro algebra acting on $\mathcal{A}_L$ which descends to $\mathcal{H}_{op}$, the generators given by $L_n = \{d, b_n^{[2]}\}$. Since L_0 is diagonal on $\mathcal{A}_L$, clearly only the subspace annihilated by L_0 can be non-trivial in $\mathcal{H}_{op}$. The algebra $\mathfrak{g} \oplus \mathfrak{h}$ of Theorem 1 also acts on $\mathcal{A}_L$ and descends to $\mathcal{H}_{op}$.

The aim now is to give a clean description of the algebra of operators in $\mathcal{H}_{op}$. It is a rather general result for gravity models¹⁷ that on $\mathcal{H}_{op}$ there is a graded-commutative associative product, $\cdot$, and a bracket, $[\cdot, \cdot]$, with respect to which $\mathcal{H}_{op}$ is a Lie superalgebra. The dot product of two operators in $\mathcal{H}_{op}$ is given by (note that in this notation the bracket does *not* denote the commutator)

$$(\mathcal{O} \cdot \mathcal{O}')(z) = \frac{1}{2\pi i} \oint_{C_z} \frac{dx}{x-z} \mathcal{O}(x) \mathcal{O}'(z).$$

Since all non-trivial cohomology states are annihilated by L_0 , any singular terms in the operator product expansion on the rhs are trivial in operator cohomology. The associativity and graded commutativity of the product at the level of cohomology follow immediately. The bracket is given by

$$[\mathcal{O}, \mathcal{O}'](z) = \oint_{C_z} \frac{dx}{2\pi i} (b_{-1}^{[2]} \mathcal{O})(x) \mathcal{O}'(z),$$

which is BRST invariance since $db_{-1}^{[2]} \mathcal{O} = L_{-1} \mathcal{O}$, and the action of L_{-1} on a field in $\mathcal{A}_L$ is equivalent to taking its derivative. The grading of the bracket, as well as the graded-Jacobi identity can be checked, along with the statement that the bracket acts as a superderivation of the dot-algebra. Together with grading, and the structures of dot and bracket, these properties identify $\mathcal{H}_{op}$ as a Gerstenhaber (or G-) algebra¹⁸.

The archetypal example of a G-algebra is the algebra of polyvector fields on a smooth manifold M , $\mathcal{P}(M)$, graded by the degree of the polyvector. More precisely, at the zeroth level in grading is just the commutative algebra (under point-wise multiplication) of polynomial functions on M , $\mathcal{A}$. At degree one are polynomial-valued vector fields on M , which of course act as derivations on the functions.

The bracket at this level can be taken as the Lie bracket of vector fields, extended to functions in the usual way. At degree two are antisymmetric derivation-valued derivations of $\mathcal{A}$ – i.e. bi-vectors on M . This construction clearly continues up to degree equal to the dimension of M . The dot product is just the wedge product on polyvectors, and the bracket is defined inductively from the Lie bracket. An obvious aim would be to understand the G-algebra of operator cohomology in this geometrical setting. The following gives exactly such a result.

Theorem 2 ¹⁰

- (i) The ghost number zero subspace $\mathcal{H}_{op}^0$ is a subalgebra, and as an sl_3 module it decomposes as $\mathcal{H}_{op}^0 \cong \bigoplus_{\Lambda \in P_+} \mathcal{L}(\Lambda)$. Thus $\mathcal{H}_{op}^0$ is a “model space” for sl_3 , and in fact is isomorphic as an algebra to the usual geometrical model – namely $\mathcal{P}^0(A)$, the space of polynomial functions on the base affine space $A \equiv N_+ \backslash SL(3)$ ¹⁹.
- (ii) This isomorphism extends to a G-algebra homomorphism $\pi : H \rightarrow \mathcal{P}(A)$, and there exists an ideal $\mathcal{I} \subset \mathcal{H}$ such that

$$0 \longrightarrow \mathcal{I} \longrightarrow \mathcal{H} \xrightarrow{\pi} \mathcal{P}(A) \longrightarrow 0$$

is an exact sequence of G-algebras.

The proof of (i) is largely direct calculation. The sl_3 decomposition of $\mathcal{H}_{op}^0$ may be read from Theorem 1. Notice that the base affine space for sl_3 is isomorphic to ²⁰ $\mathcal{C}[x^i, y_i] / \langle x^i y_i \rangle$, i.e. the space of polynomials in the 6 variables x^i, y_i modded out by a single relation $x^i y_i = 0$, where x^i and y_i transform in the **3** and $\bar{\mathbf{3}}$ of sl_3 respectively. Denote the representatives of $\mathcal{H}_{op}^0$ which transform in these representations by Ψ_{x^i} and Ψ_{y_i} . As discussed earlier, in cohomology these operators generate under dot product a commutative and associative algebra. Denote this algebra by $\mathcal{R}$. One easily sees from Theorem 1 that addition of Liouville momenta is inconsistent with a singlet in the product of these representatives – alternatively one can directly calculate $\Psi_{x^i} \Psi_{y_i}$ and show that it is d -trivial. So, a given monomial in the algebra generated by these operators,

$$\Psi_{x_1^i} \cdot \dots \cdot \Psi_{x_m^i} \cdot \Psi_{y_j^1} \cdot \dots \cdot \Psi_{y_j^n}$$

transforms under $\mathfrak{g} \oplus \mathfrak{h}$ exactly as the tensor product representation, and thus decomposes either by contraction – which by associativity and the calculation mentioned above must vanish in cohomology – or by antisymmetrization which by commutativity clearly vanishes. Thus the only sl_3 representation which can possibly survive is precisely the “top” one (consistent with Theorem 1), and if all dot products of the highest weight operators Ψ_{x^1} and Ψ_{y_3} are non-trivial in cohomology then the algebra $\mathcal{R}$ is isomorphic to $\mathcal{P}^0(A)$ as wanted. Since these two operators are sl_3 highest weight, they have Liouville momenta determined by $-i\Lambda^L = \Lambda^M$. Hence they have the form

$$\begin{aligned} \Psi_{x^1} &= P_{x^1} e^{i\Lambda_1 \cdot \phi^+} \\ \Psi_{y_3} &= P_{y_3} e^{i\Lambda_2 \cdot \phi^+}, \end{aligned}$$

where $\phi^\pm = \phi^M \pm i\phi^L$, and where the prefactor P denotes a level 2 operator built from the ghosts, $\partial\phi^\pm$, and derivatives thereof. The precise expressions for the prefactors are not needed, just the fact that for any representative in cohomology these prefactors must contain a term quadratic in $i\partial\phi^-$ – and indeed an independent combination in each prefactor. Such terms, monomials in the prefactor built purely from $i\partial\phi^-$, will be referred to as “leading order”, and for these highest weight operators one finds

$$\begin{aligned} P_{x^1}|_{\text{leading}} &= \frac{3}{2}((i\partial\phi^{-,1})(i\partial\phi^{-,1}) + \sqrt{3}i\partial\phi^{-,1}i\partial\phi^{-,2}) \\ P_{y_3}|_{\text{leading}} &= \frac{3}{4}((i\partial\phi^{-,1})(i\partial\phi^{-,1}) - 3((i\partial\phi^{-,2})(i\partial\phi^{-,2})). \end{aligned}$$

Consider now the dot product of m Ψ_{x^1} ’s and n Ψ_{y_3} ’s,

$$\Psi_{x^1} \cdots \Psi_{y_3} = P_{mn} e^{i(m\Lambda_1 + n\Lambda_2) \cdot \phi^+},$$

where the prefactor P_{mn} is a level $2(m+n)$, ghost number zero operator built as before. There are no contractions between the purely- ϕ^+ exponentials in computing the dot product. There will be contractions between the prefactors and the exponentials, and between prefactors. A moment’s thought shows that these cannot give rise to leading terms: only the first non-singular term (from the Taylor series expansion of the residue) contributes to the dot product, and this necessarily either has higher derivatives, or non-zero powers of $i\partial\phi^+$ from differentiating the exponentials. Thus there is a unique source, providing a manifestly non-zero leading term, which is the contribution from the no-contraction term.

Hence, the dot product $\Psi_{x^1}^m \Psi_{y_3}^n$ has a non-zero leading term, and a similar argument using the explicit form of d shows that it is non-trivial in cohomology. This completes the proof of part (i).

The extension of this step to the complete G-algebra as in (ii) requires a more detailed understanding of polyvectors on base affine space, and sufficient calculation to identify the generators in cohomology. This may certainly be done, the reader may consult ¹⁰. Let me here just explain the homomorphism, π , following ¹⁷. Since at the zeroth grade this is an isomorphism, I will use X to denote both a given monomial in x^i and y_i as well as the corresponding cohomology representatives, unless there is the possibility of confusion. Now, since $[\mathcal{H}_{op}^1, X] \in \mathcal{H}_{op}^0$, for all $X \in \mathcal{H}_{op}^0$, the G-algebra structure may be used to extend π to $\mathcal{H}_{op}^1$ via

$$[\pi(\Psi^{(1)}), X] \equiv \pi([\Psi^{(1)}, X]). \quad (7)$$

Notice that the square bracket denotes the bracket structure in $\mathcal{H}_{op}$ as well as in $\mathcal{P}(A)$, there will be no possibility of confusion due to the explicit use of the projection, π . Having determined this map for ghost number 1 it may be extended to ghost number 2, and so on, exactly as above.

By construction the map $\pi : \mathcal{H}_{op} \rightarrow \mathcal{P}(A)$ is a dot-algebra homomorphism, as is easy to show inductively. Suppose it is true up to some ghost number, then if $\Psi \cdot \Psi'$

is ghost number one higher (for any $\Psi, \Psi' \in \mathcal{H}_{op}^*$),

$$[\pi(\Psi \cdot \Psi'), X] = \pi([\Psi \cdot \Psi', X]) \quad (8)$$

$$= \pi(\Psi \cdot [\Psi', X]) + (-1)^{|\Psi'|} \pi([\Psi, X] \cdot \Psi') \quad (9)$$

$$= \pi(\Psi) \cdot \pi([\Psi', X]) + (-1)^{|\Psi'|} \pi([\Psi, X]) \cdot \pi(\Psi') \quad (10)$$

$$= [\pi(\Psi) \cdot \pi(\Psi'), X] \quad (11)$$

where the third equality uses the induction hypothesis. To show that the map π is actually a G-algebra homomorphism is equally straightforward. Note that for any $\Psi \in H^*$,

$$\pi([\Psi, X]) \equiv [\pi(\Psi), X],$$

simply by the definition (7). Since π is a ring isomorphism this is also true if X is replaced by any operator in H^0 . Again suppose it is true up to some ghost number, and that (for any $\Psi, \Psi' \in H^*$) $[\Psi, \Psi']$ has ghost number one higher. Then

$$[\pi([\Psi, \Psi']), X] = \pi([\Psi, \Psi'], X) \quad (12)$$

$$= \pi([\Psi, [\Psi', X]]) - (-1)^{|\Psi'|} \pi([\Psi, X], \Psi') \quad (13)$$

$$= [\pi([\Psi, X]), \pi(\Psi')] - (-1)^{|\Psi'|} [\pi(\Psi), \pi([\Psi', X])] \quad (14)$$

$$= [[\pi(\Psi), X], \pi(\Psi')] - (-1)^{|\Psi'|} [\pi(\Psi), [\pi(\Psi'), X]] \quad (15)$$

$$= [[\pi(\Psi), \pi(\Psi')], X]. \quad (16)$$

Thus this π is in fact the homomorphism required. $\square$

As a final remark, it is worth noting that the general construction of the G-algebra in string theories, as alluded to above, leads to a very special subset; namely, the Batalin-Vilkovisky (BV-) algebras^{21 22 23}, for which there is a nilpotent second order derivation Δ such that

$$[a, b] = (-1)^{|a|} \left(\Delta(a \cdot b) - (\Delta a) \cdot b - (-1)^{|a|} a \cdot (\Delta b) \right),$$

for any a, b in the algebra. The role of Δ is played by the ghost zero mode $b_0^{[2]}$. It is possible to show¹⁰ that $\mathcal{P}(A)$ has a BV-algebra structure, and in fact the sequence in the statement of Theorem 2 (ii) is an exact sequence of BV-algebras which splits as a sequence of $\iota(\mathcal{P}(A))$ dot modules, where $\iota : \mathcal{P}(A) \rightarrow \mathcal{H}$ is a dot algebra homomorphism such that $\pi \circ \iota = \text{id}$.

Acknowledgements

In various calculations throughout this work the Mathematica package `OPedefs` of C. Thielemans²⁴ has been extremely useful. I would like to thank the organizers of the conference “Confronting the Infinite” for the opportunity to present this work. The conference celebrated the work of two outstanding mathematical physicists, Bert Green and Angas Hurst, the title apparently *not* referring to age but rather the capacity to suffer through seminars. I hope they will find this little contribution amusing, but in any case I look forward to having another go when we celebrate their next milestone.
